et al. (2019)

Estimating LW cloud feedbacks from CALIPSO GOCCP

Opposite sign in feedback between observations & models

- **Observations:** CALIPSO data (2008-2014)
- **Model simulation short-term :** LMDZ model+lidar simulator in present-day (AMIP) climate
- **Model simulation long-term:** present day (AMIP) and future (AMIP + 4K)

Vaillant de Guélis et al. (2018)

GOAL: Derive a short-term (interannual) LW high cloud feedback

- A. What are the ingredients necessary for the computation?
- B. Compute and compare the “inferred” feedback with active and passive observational data sets**
 - i. Decompose the feedback into different high cloud regimes
- C. Ongoing:
 - i. Constructing long-term feedback with Cloud Controlling Factors
 - ii. Evaluating GISS ModelE3
- D. Summary

Data sets for LW high cloud feedback calculation

Data set & method requirements

- ✓ Compatible with climate model output (i.e. gridded monthly means)
- ✓ Combined clouds and TOA radiative fluxes
 - ✓ Extract high clouds only
 - High Cloud Cover (HCC)
 - ✓ Isolate the changes in LW CRE *due to clouds only*

Surface temperature anomalies

Global

High cloud feedback from CALIPSO GOCCP

2°x 2° gridded monthly mean anomalies (2007-2018)

$$\underbrace{\frac{dCRE_{LW,CLD}}{dHCC}}_{\text{Sensitivity of } \Delta CRE \text{ (from cloud changes) to } \Delta HCC} \frac{dHCC}{dT} \cong \frac{dCRE_{LW,HCC}}{dT}$$

Sensitivity of ΔCRE (from cloud changes) to ΔHCC

✓ LW CRE increases with increased high clouds

High cloud feedback from CALIPSO GOCCP

2°x 2° gridded monthly mean anomalies (2007-2018)

$$\frac{dCRE_{LW,CLD}}{dHCC} \underbrace{\frac{dHCC}{dT}}_{\text{Interannual variability of HCC}} \cong \frac{dCRE_{LW,HCC}}{dT}$$

Interannual variability of
HCC

✓ Distinct El Niño signature

High cloud feedback from CALIPSO GOCCP

2°x 2° gridded monthly mean anomalies (2007-2018)

$$\frac{dCRE_{LW,CLD}}{dHCC} \frac{dHCC}{dT} \cong \underbrace{\frac{dCRE_{LW,HCC}}{dT}}_{\text{High cloud cover feedback } (\sim \lambda_{HCC})}$$

- ✓ **Negative** tropical mean (consistent with *Raghuraman et al. 2024*)
- ✓ **Near-zero** global mean

Avg [Tr(-0.77 ± 0.52) | GI(0.04 ± 0.02)]

Comparing feedbacks between GOCCP and FBCT

CALIPSO GOCCP

Avg [Tr(-0.77) | GI(0.04)]

CERES FBCT

Avg [Tr(-0.66) | GI(0.15)]

Corr [Tr(0.92) | GI(0.87)]

Difference (GOCCP – FBCT)

Avg [Tr(-0.11) | GI(-0.11)]

✓ High correlation, magnitudes differ between data sets

Decomposing feedback for different high cloud regimes

$$\frac{dCRE_{LW,CLD}}{dHCC} \sum_{regime}^j \frac{dHCC_{regime}}{dT} \cong \frac{dCRE_{LW,HCC}}{dT}$$

CALIPSO GOCCP (2007-2018)

Descent (Cirrus)

Avg [Tr(-0.28) | Gl(0.09)]

Weak ascent (Stratiform)

Avg [Tr(-0.45) | Gl(-0.17)]

Strong ascent (Convection)

Avg [Tr(-0.04) | Gl(0.12)]

✓ The **descent regime has largest contribution** to the global feedback due to how frequently subsidence occurs

Ongoing: High cloud controlling factors (CCFs)

$$\frac{dCRE_{LW,CLD}}{dHCC} \sum_{i=1} \frac{\partial HCC}{\partial CCF_i} \underbrace{\frac{\partial CCF_i}{\partial T}}_{\text{CCF contribution to interannual variability of HCC}} \cong \frac{dCRE_{LW,HCC}}{dT}$$

CCF contribution to
interannual variability of
HCC

High CCFs from ERA5 (Kemsley et al. 2024):

- ❑ Surface temperature (T_{sfc})
- ❑ Free Tropospheric Relative Humidity (RH_{700})
- ❑ Vertical velocity at 300 hPa (ω_{300})
- ❑ Upper Tropospheric Stability (UTS)

$$UTS = \theta_{200} - \theta_{500}$$

Ongoing: High cloud controlling factors (CCFs)

$$\frac{dCRE_{LW,CLD}}{dHCC} \sum_{i=1} \frac{\partial HCC}{\partial CCF_i} \frac{\partial CCF_i}{\partial T} \cong \frac{dCRE_{LW,HCC}}{dT}$$

Ongoing: High cloud controlling factors (CCFs)

$$\frac{dCRE_{LW,CLD}}{dHCC} \sum_{i=1} \frac{\partial HCC}{\partial CCF_i} \frac{\partial CCF_i}{\partial T} \cong \frac{dCRE_{LW,HCC}}{dT}$$

Ongoing: High cloud controlling factors (CCFs)

$$\frac{dCRE_{LW,CLD}}{dHCC} \sum_{i=1} \frac{\partial HCC}{\partial CCF_i} \frac{\partial CCF_i}{\partial T} \approx \boxed{\frac{dCRE_{LW,HCC}}{dT}}$$

✓ High (88%) correlation between methods

Difference between *inferred* and **CCF** approaches could emerge from:

- (1) Inaccuracies from reanalyses
- (2) Potentially missing / covarying CCFs

Ongoing: Evaluating GISS ModelE3

2°x 2° gridded monthly mean anomalies (2007-2014)

CALIPSO

E3-G-p101 (AMIP)

✓ 81% correlated

Sensitivity of LW to HCC is very similar between observations and E3

Summary & Future work

Contact: jap2335@columbia.edu

- Active-based remote sensing measurements well-represent the LW high cloud cover feedback
 - **Near-zero** global short-term LW high cloud cover feedback
- High thin clouds have an important impact on the feedback
- Important given how high clouds are biased in CMIP models
- Future work:
 1. Isolate cloud property contributions to feedback
 2. Explore covariance between high cloud controlling factors
 3. Evaluate multiple E3 model members / extrapolate to CMIP6 models
